#### 1 Conventions

#### **Math Notation**

- $x \in \{0, 1\}^r$ : x is a vector of form e.g. (0, 1, 1, 0, ..., 1, 0) of length r.
- $\mathbf{1}(\cdot)$ : indicator function 1 when arg is true, 0 when arg is false.
- Boldface capital letters are matrices, *e.g.*  $\mathbf{A} = \mathbf{U}\mathbf{W}\mathbf{V}^{\mathsf{T}}$
- log is base e by default  $\rightarrow$  entropy in nats.

# Ng CS229 / DeepLearning.ai

- m: number of training examples in the dataset
- *n* : dimension of training examples
- $x^{(i)} \in \mathbb{R}^n$ :  $i^{th}$  training example (*column* vector),  $1 \le i \le m$
- $y^{(i)}$ :  $i^{th}$  output (*column* vector),  $1 \le i \le m$
- $x_i : j^{th}$  component of a training example,  $1 \le j \le n$ .
- $\mathbf{X} \in \mathbb{R}^{n \times m}$ : (input/design) matrix (training examples are *column* vectors)<sup>1</sup>
- $X \in \mathbb{R}^{m \times n}$ : (input/design) matrix (training examples are *row* vectors)

<sup>&</sup>lt;sup>1</sup>Note our non-conventional definition of the design matrix **X**. The more conventional version is denoted **X**.

# 2 Linear Regression

#### 2.1 Basics

- Hypothesis  $h_{\theta}(x) = \theta_0 + \theta_1 x_1 + \theta_2 x_2 + \dots = \sum_{j=0}^n \theta_j x_j \equiv \theta^{\top} x$ , where  $x_0 = 1$ .
- Cost function

$$J(\theta) = \frac{1}{2} \sum_{i=1}^{m} \left( h_{\theta}(x^{(i)}) - y^{(i)} \right)^{2}$$
 (2.1)

• Analytically solve via normal equations, where **X** is the augmented  $(n + 1) \times m$  design matrix

$$\vec{\theta} = (\mathbf{X}\mathbf{X}^{\mathsf{T}})^{-1}\mathbf{X}\,\vec{y} \tag{2.2}$$

where  $\vec{\theta}$  and  $\vec{y}$  are column vectors of the n+1 weights and m outputs, respectively.

# 3 Logistic Regression

## 3.1 2 classes

With 2 labels  $y \in \{0, 1\}$  and m training examples  $x^{(i)}, 1 \le i \le m$ , we have

$$h_{\theta}(x) = \frac{1}{1 + e^{-\theta^{\top} x}} \tag{3.1}$$

$$p(y|x;\theta) = (h_{\theta}(x))^{y} (1 - h_{\theta}(x))^{1-y}$$
(3.2)

$$L(\theta) = \prod_{i=1}^{m} (h_{\theta}(x^{(i)}))^{y^{(i)}} (1 - h_{\theta}(x^{(i)}))^{1 - y^{(i)}}$$
(3.3)

$$l(\theta) = \log L(\theta) = \sum_{i=1}^{m} y^{(i)} \log h_{\theta}(x^{(i)}) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)}))$$
(3.4)

with deriv

$$\frac{\partial}{\partial \theta_i} l(\theta) = x_j^{\mathsf{T}} (y - h_{\theta}(x)) \tag{3.5}$$

We can't minimize the log-likelihood analytically, so we must use numerical optimization.

The log-likelihood is just the cross entropy

$$H(p,q) = -\sum_{i} p_i \log q_i \tag{3.6}$$

with p the actual outputs, and q the hypothesis  $h_{\theta}(x)$ 

#### 3.2 2+ classes

**One-versus-all:** For k classes, do k normal log regs. Each has two classes: the target class, and all the rest. New examples are classified by whichever of these k log regs. has highest score.

**Softmax regression:** Model classification cases as *multinomial* distribution. For *k* classes, hypothesis is *k*-dim vector

$$h_{\theta}(x) = \frac{1}{\sum_{l=1}^{k} \exp(\theta^{(l)T} x)} \times \left[ \exp(\theta^{(1)T} x), \dots, \exp(\theta^{(k)T} x) \right]$$
(3.7)

The log-likelihood is

$$l(\theta) = -\sum_{i=1}^{m} \sum_{l=1}^{k} \mathbf{1}(y^{(i)} = l) \log \frac{\exp(\theta^{(l)T} x)}{\sum_{m=1}^{k} \exp(\theta^{(m)T} x)}$$
(3.8)

TODO: show how 2-class log reg cost func can be written this way. write down deriv of cost func. clean up notation.

# 4 Gaussian Discriminant Analysis (GDA) and Naive Bayes

**Generative algorithm**: Instead of modeling p(y|x), model p(y) and p(x|y), then get posterior p(y|x) via Bayes' theorem.

#### 4.1 GDA

Can use GDA for classification problem when input features are continuous-val random vars. Models p(x|y) as multivariate Gaussian. Model is

$$y \sim \text{Bernoulli}(\phi)$$

$$x|y = 0 \sim \mathcal{N}(\mu_0, \Sigma)$$

$$x|y = 1 \sim \mathcal{N}(\mu_1, \Sigma)$$
(4.1)

TODO: finish —

# 4.2 Naive Bayes (for text classification)

For training examples  $x \in \{0, 1\}^n$  (a *vocabulary*<sup>2</sup> of length n), assume the components of an example,  $x_j$ , are conditionally independent given y (*Naive Bayes assumption*).

$$p(x_1, \dots, x_n | y) = \prod_{i=1}^n p(x_i | y)$$
(4.2)

<sup>&</sup>lt;sup>2</sup>the  $j^{th}$  entry is 1 if the example contains the  $j^{th}$  word in the vocabulary. **Example**: If the vocab is {cats, rats, bats}, then n = 3, and a training example that contains "cats", "rats", but not "bats", would be x = (1, 1, 0).

Model is parameterized by

$$\phi_y = p(y=1),$$
  $\phi_{j|y=1} = p(x_j = 1|y=1),$   $\phi_{j|y=0} = p(x_j = 1|y=0)$  (4.3)

where  $j \in (1, n)$ , for a total of 2n + 1 parameters. Likelihood is

$$L(\phi_{y}, \{\phi_{j|y=1}, \phi_{j|y=0}\}_{j=1}^{n}) = \prod_{i=1}^{m} p(x^{(i)}, y^{(i)})$$
(4.4)

which has MLE values

 $\phi_{j|y=1}$  = fraction of spam (y=1) in which word j appears  $\phi_{j|y=0}$  = fraction of non-spam (y=0) in which word j appears  $\phi_y$  = fraction of training examples that are spam (4.5)

To make predictions, we don't need the evidence p(x); we just need to compare

$$p(y = 1|x) \propto p(x|y = 1)p(y = 1)$$
  
 
$$p(y = 0|x) \propto p(x|y = 0)p(y = 0)$$
 (4.6)

and pick the class that has the higher value (un-normalized posterior).

TODO: finish — show how last two egs are actually calculated

#### 5 Bias/Variance Tradeoff

- **High bias**: underfitting. high training error and test error.
- **High variance**: overfitting. *low* training error and *high* test error

Can't use the test set to decide on values of hypers (*e.g.* number of parameters in model) because "we could just tweak the values of the hypers until the estimator performs optimally [on the test set]".

Cross-validation allows you to do model scoring (on frequentist stats, versus *e.g.* info criteria for Bayesian stats.. **TODO: verify i know what i'm talking about**).

Can average together multiple models with high capacity (low bias, but high variance). The result of combining is to *reduce* the variance of the combined model.

#### 6 Model Assessment

#### 6.1 Classification

#### 6.1.1 Precision/Recall

For 2 classes, with  $\{TN, FN, FP, TP\} = \{\text{true negatives, false negatives, false positives, true positives}\},$  we have the *loss* or *confusion matrix*:

$$\begin{pmatrix}
TN & FP \\
FN & TP
\end{pmatrix},$$
(6.1)

where the rows/columns are actual/predicted numbers of examples not-in-class (negative), or in-class (positive). We define the *precision* and *recall*:

precision = 
$$\frac{TP}{TP + FP}$$
, recall =  $\frac{TP}{TP + FN}$ . (6.2)

**Precision** is ability of classifier to not classify actual negatives as positive (*i.e.* low false positives). So *e.g.* if positive is "person doesn't have cancer", we want high precision.

**Recall** is ability of classifer to find all positive samples.

# 6.1.2 Receiver operating characteristic curve (ROC)

True Positive Rate (TPR): same as recall

*True Negative Rate (TNR):* fraction of actual negatives that are classified as negative TN/(TN + FP)

False Positive Rate (FPR): 1 - TNR

ROC plots TPR versus FPR.

**TODO:** F score

#### 6.2 Misc

k: number of model parameters

• Akaike Information Criteria (AIC):  $2k - 2 \ln L(\theta)$ TODO: how to apply in practice

## 7 K-means

- Setup: Select any K points from data to serve as initial centroids of the clusters.
- Repeat until (stopping criteria: *e.g.* no points change clusters, sum of distances is minimized, some total number of iterations..):
  - 1. Assign each datapoint to the cluster with closest centroid.
  - 2. Compute *K* new centroids, each the mean of the datapoints in its cluster.

#### 8 PCA

PCA is unsupervised technique for finding directions of most variance in dataset. The *principal components* are a set of *n* orthonormal *n*-dim basis vects along the directions of maximum variance, ordered by decreasing variance in their directions.

#### To calc:

• via eigenvectors: Principal components of *de-meaned n*×*m* design matrix **X** are the eigenvectors of the covariance matrix of **X**,  $\mathbf{C}_{\mathbf{X}} = \frac{1}{m} \mathbf{X} \mathbf{X}^{\top}$ .

• via SVD: Define  $\mathbf{Y} = \frac{1}{\sqrt{m}} \mathbf{X}^{\mathsf{T}}$ , and take its SVD A.3, which is  $\mathbf{Y} = \mathbf{U}\mathbf{W}\mathbf{V}^{\mathsf{T}}$ . Then  $\mathbf{U}^{\mathsf{T}}$  is  $n \times m$  matrix that projects  $\mathbf{X}$  onto its principal components,  $\mathbf{W}$  is the matrix of principal comp values, and  $\mathbf{V}$  is orthonormal matrix of the principal components. TODO: Verify/fix statement on  $\mathbf{U}$  projection.

#### 9 Time Series

## 9.1 Stationarity

**Definition 1 (Second Order Stationarity)** is when correlation between sequential observations is only a function of the lag.

• **Dickey-Fuller test:** tests for stationarity of AR model. Null hypothesis is "series is *non-stationary*".

#### 9.2 ARCH

Box-Jenkins: systematic methodology for identifying and estimating models that can incorporate both AR and MA.

#### 10 Gaussian Processes

#### 11 Neural Networks

## 11.1 Hyperparameters

Hypers: learning rate, num iteractions, num hidden layers, num units in each layer, choice of activation function, amout of momentum, minibatch size, regularization type and amount.

#### 11.2 Bias/Variance

Bias/variance is less of a *tradeoff* in neural network training, since we have a number of methods to reduce both independently.

- Reduce bias (train set perf): Bigger network, train longer, (NN arch search)
- **Reduce variance (dev set perf):** More data, regularization.. (when changed go back and retune bias)

## 12 Variational Methods

### **Preliminary section!**

If our prior is not a conjugate prior to our likelihood, we can't compute posterior in closed form. Try:

- approximate intractable posterior  $p(\vec{\theta}|\vec{y})$  with tractable  $q(\vec{\theta}|\gamma)$ .
- Adjust  $\gamma$  to minimize  $KL\left[p(\vec{\theta}|\vec{y})||q(\vec{\theta}|\gamma)\right] \rightarrow \text{complicated}$ , since we don't know  $p(\vec{\theta}|\vec{y})$ . Eventually will use *Expectation Propagation* to solve.
- Adjust  $\gamma$  to minimize  $KL[q(\vec{\theta}|\gamma)||p(\vec{\theta}|\vec{y})] \rightarrow \text{simpler: } Variational \ Bayes.$
- Variational Bayes: minimizing  $KL\left[q(\vec{\theta}|\gamma)||p(\vec{\theta}|\vec{y})\right]\iff$  maximizing ELBO  $\mathcal L$
- ullet note the *latent/hidden variables* helping us are the  $ec{ heta}$

# Appendix A Math Stuff

#### A.1 Matrix Stuff

#### A.1.1 Partitioned Matrix Inversion

Given block decomposition of matrix into submatrices A, B, C, D, the inverse is:

$$\begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{C} & \mathbf{D} \end{pmatrix}^{-1} = \begin{pmatrix} \mathbf{M} & -\mathbf{M}\mathbf{B}\mathbf{D}^{-1} \\ -\mathbf{D}^{-1}\mathbf{C}\mathbf{M} & \mathbf{D}^{-1} + \mathbf{D}^{-1}\mathbf{C}\mathbf{M}\mathbf{B}\mathbf{D}^{-1} \end{pmatrix}, \tag{A.1}$$

where

$$\mathbf{M} = \left(\mathbf{A} - \mathbf{B}\mathbf{D}^{-1}\mathbf{C}\right)^{-1} \tag{A.2}$$

(NB compare with Matt Headrick's compendium inversion formula)

## A.2 Gaussians

# A.2.1 Partitioned Gaussians: Conditional and Marginal Distributions

From BISHOP, sections 2.3.1 - 2.3.2.

Consider a joint Gaussian distribution,  $\mathcal{N}(\vec{x}|\vec{\mu}, \Sigma)$  with  $\Lambda \equiv \Sigma^{-1}$  and

$$\vec{x} = \begin{pmatrix} \vec{x}_a \\ \vec{x}_b \end{pmatrix}, \quad \vec{\mu} = \begin{pmatrix} \vec{\mu}_a \\ \vec{\mu}_b \end{pmatrix}$$
 (A.3)

$$\Sigma = \begin{pmatrix} \Sigma_{aa} & \Sigma_{ab} \\ \Sigma_{ba} & \Sigma_{bb} \end{pmatrix}, \quad \Lambda = \begin{pmatrix} \Lambda_{aa} & \Lambda_{ab} \\ \Lambda_{ba} & \Lambda_{bb} \end{pmatrix}. \tag{A.4}$$

(That is, the vector  $\vec{x}$  is partitioned into  $\vec{x}_a$  and  $\vec{x}_b$ , which induces a block partitioning of the covariance matrix  $\Sigma$ .)

The conditional distribution is:

$$p(\vec{x}_a|\vec{x}_b) = \mathcal{N}(\vec{x}|\vec{\mu}_{a|b}, \mathbf{\Lambda}_{aa}^{-1}) \tag{A.5}$$

$$\vec{\mu}_{a|b} = \vec{\mu}_a - \Lambda_{aa}^{-1} \Lambda_{ab} (\vec{x}_b - \vec{\mu}_b) \tag{A.6}$$

The marginal distribution is:

$$p(\vec{x}_a) = \mathcal{N}(\vec{x}_a | \vec{\mu}_a, \mathbf{\Sigma}_{aa}) \tag{A.7}$$

# A.2.2 Bayes' theorem for Gaussian variables

From BISHOP, section 2.3.3. NB This is known as a *linear Gaussian model*.

Given a marginal Gaussian distribution for  $\vec{x}$  and a conditional Gaussian distribution for  $\vec{y}$  given  $\vec{x}$  in the form:

$$p(\vec{x}) = \mathcal{N}(\vec{x}|\vec{\mu}, \mathbf{\Lambda}^{-1}) \tag{A.8}$$

$$p(\vec{y}|\vec{x}) = \mathcal{N}(\vec{y}|\mathbf{A}\vec{x} + \vec{b}, \mathbf{L}^{-1}), \tag{A.9}$$

we have

$$p(\vec{y}) = \mathcal{N}(\vec{y}|\mathbf{A}\vec{\mu} + \vec{b}, \mathbf{L}^{-1} + \mathbf{A}\boldsymbol{\Lambda}^{-1}\mathbf{A}^{\mathsf{T}})$$
(A.10)

$$p(\vec{x}|\vec{y}) = \mathcal{N}(\vec{x}|\mathbf{\Sigma}\{\mathbf{A}^{\mathsf{T}}\mathbf{L}(\vec{y} - \vec{b}) + \mathbf{\Lambda}\vec{\mu}\}, \mathbf{\Sigma})$$
(A.11)

where

$$\Sigma \equiv (\mathbf{\Lambda} + \mathbf{A}^{\mathsf{T}} \mathbf{L} \mathbf{A})^{-1} \tag{A.12}$$

# A.3 Singular value decomposition

An  $M \times N$  matrix **A** can be written as  $\mathbf{U}\mathbf{W}\mathbf{V}^{\mathsf{T}}$ , where **U** is  $M \times N$ , **W** is  $N \times N$  and diagonal, and **V** is  $N \times N$  and orthonormal.

If A is square, V are its eigenvectors, and W are its eigenvalues...

Uses:

• If  $M \ge N$ , cols of **U** are an orthonormal basis for space spanned by cols of **A** 

TODO: finish —

#### A.4 Matrix derivatives

$$\frac{\partial}{\partial \vec{x}} \left( \vec{x}^{\mathsf{T}} \vec{a} \right) = \frac{\partial}{\partial \vec{x}} \left( \vec{a}^{\mathsf{T}} \vec{x} \right) = \vec{a} \tag{A.13}$$

TODO: review understanding of this (I recall this expression not enough to answer my questions on a formula derivation) and give examples.

# Appendix B The Linear Regression Hierarchy

Linear regression starting from maximum likelihood, through variational Bayes.

#### **B.1** Maximum likelihood

Maximize likelihood  $p(y|\theta; \beta)$  wrt  $\theta$ ,  $\beta$ .

# B.2 Maximum a posteriori

Introduce prior  $p(\theta; \alpha) = \exp(-\alpha \theta^{T} \theta)$ . Find  $\theta$  by maximizing  $p(y|\theta; \beta)p(\theta; \alpha)$  wrt  $\theta$ . Q: what is proper way to estimate  $\beta$  and  $\alpha$  here?

# **B.3** Full Bayesian (stationary prior)

Calc posterior  $p(\theta|y) = p(y|\theta; \beta)p(\theta; \alpha)/p(y; \alpha, \beta)$ , where  $p(y; \alpha, \beta) = \int_{\theta} p(y|\theta; \beta)p(\theta; \alpha)$  is the evidence. Determine values of hypers  $\alpha, \beta$  by maximizing evidence. This is difficult to do directly, as derivs wrt  $\alpha, \beta$  are hard to compute, so use EM algorithm.

# **B.4** Variational Bayes (non-stationary prior)
